

If you test the trained algorithm, it should be able to solve ≥ 94% of the episodes within the maximum step limit. We even recorded video frames during training, and the agent clearly knows what it is doing when you watch it in real time. We have omitted a lot of this accessory code to keep the text clear; please see the GitHub repository for the complete code.

10.6.1. Maximum entropy learning

We are using an epsilon-greedy policy with epsilon set to 0.5, so the agent is taking random actions 50% of the time. We tested using a number of different epsilon levels but found 0.5 to be about the best. If you train the agent with epsilon values ranging from a low of 0.01, to 0.1, to 0.2, all the way to a high of say 0.95, you will notice the training performance follows
