of the 'living room' sensor, which is a 'sensor' located within a 'space' that is a 'room', as defined by the ontology.

> ***NOTE***
>
> A GraphQL schema is itself a model of the physical system that encodes the ontology. The schema's type system enforces this ontology at run time.

By using GraphQL with an established ontology like RealEstateCore, I can build a flexible, powerful API that accurately models the reality of my home, ensuring it is both useful for my own applications and compatible with the broader smart home ecosystem.

TRY IT OUT: BUILD A GRAPHQL API

Listing 5.4 shows an example of how you can create a simple GraphQL API that orchestrates two calls: a call to a geocoding API to determine the co-ordinates of a given city, and once it has these, it calls the Open Meteo API to get the forecast temperature and rainfall for the next seven days, exposing a single query to clients to get the forecast for a given city.
