```
            result.append( (str(year), f"{year}-{year+9}") )

        return result

    def queryset(self, request, queryset):
        start = self.value()
        if start is None:
            return queryset

        start = int(start)
        result = queryset.filter(
            birth__gte=date(start, 1, 1),
            birth__lte=date(start + 9, 12, 31),
        )

        return result
...
class MusicianAdmin(admin.ModelAdmin):
    list_display = ("id", "last_name", "first_name", "birth",
        "show_weekday", )
    list_filter = (DecadeListFilter, )
```

Add a tuple containing the base year of the decade and a display string.

Get the filtered value, checking for None (meaning no filter).

Run a subfilter on the QuerySet, restricting the birth field to the chosen decade, starting on January 1st and going through December 31, 9 years later.

Add a birth field column to the listing.

Add the new DecadeListFilter to the admin.ModelAdmin class.

To make it a little more obvious, the code in the preceding listing also adds `birth` to the `list_display` attribute, so you can see if the decade filter is working. With the code in place, start your development server and take a look at your new `Musician` listing page. Figure 5.9 shows a page filtered from 1940–1949.
