The view function first determines whether it was invoked through a GET or a POST call, displaying the form in the first case and handling the submission in the second. If the form validates, the view redirects the user to another page. If the form doesn't validate, error information gets added to the form, and the GET code gets called again. Figure 7.2 details this process.

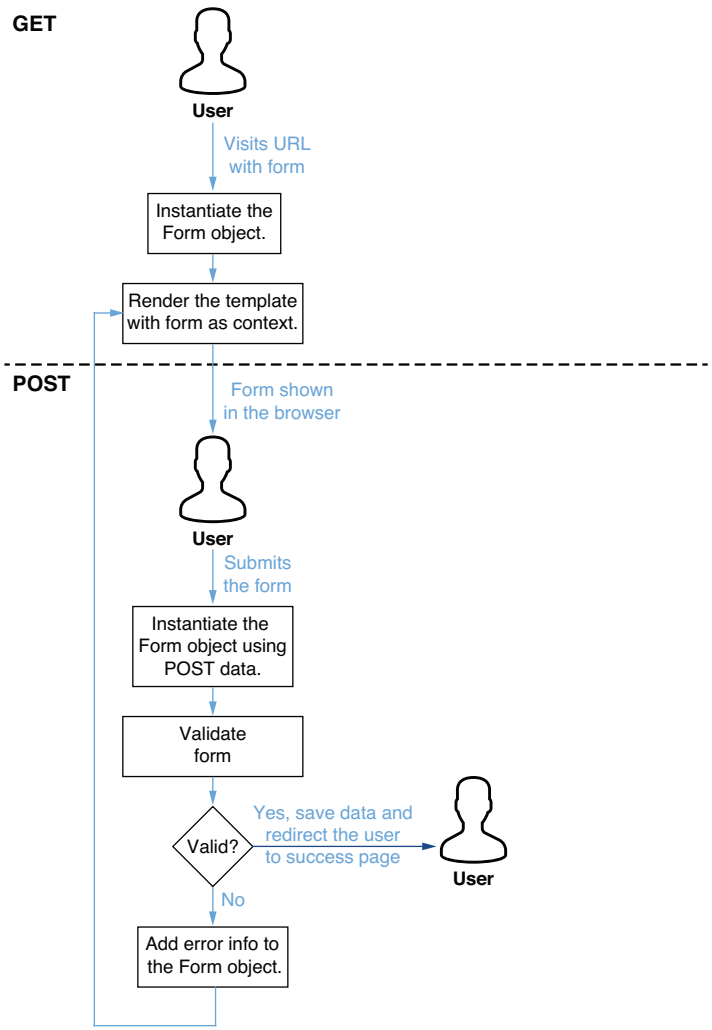

Figure 7.2 Logic flow for a view that handles form submission

Let's put this into practice by writing a view that uses your `CommentForm`. The `comment()` view is divided into three parts: a GET handler, a POST handler, and the form renderer. The view first checks if the HTTP method was GET, and if so, it instantiates a new
