will render for you. You can still use `Form` objects, but you need to write the corresponding HTML in full. The key to getting this to work is the correct use of `id` and `name` attributes on the tags. Django expects the field `name` to show up as the tag's `name` attribute and the tag's ID attribute to contain id-underscore-field.

The `form` object in the template provides access to each individual field via dot-notation. Each field has attributes for the value of the field, corresponding help text, and any associated error message. Each of these pieces can be accessed in your template to help you render beautiful content.

The following code is a sample Bootstrap field for entering a first name:

```
<div class="form-group">
    <label for="first_name">First name</label>

    <input type="text" class="form-control"
        id="id_first_name" name="first_name"
        aria-describedby="first_name_help"
        placeholder="First name"
        {% if form.first_name.value %}
            value="{{ form.first_name.value }}"
        {% endif %}
    >

    <small id="first_name_help"
        class="form-text text-muted">
            If you are Cher or Madonna, enter your name
            in the last name field
    </small>

    {% if form.errors.first_name %}
        <small class="text-danger">
            {{ form.errors.first_name }}
        </small>
    {% endif %}
</div>
```

That's a lot of code, isn't it? The `Form` does so much for you: properly populating the field, showing help text, and errors when they occur. If you can get your forms to be beautiful enough through CSS alone, you can write a lot less HTML. Depending on your style toolkit, there may be third-party libraries that build on top of `Form`, doing the work for you. They're worth checking out before writing all that HTML.

7.1.4 New in Django 5: Reusable field group templates

Having to write HTML by hand due to styling is a step backward. Django 5 recognizes this and adds a new feature: reusable field group templates. In Django 5, the structure of a form field is determined by a template. This template contains the tags for labels and inputs along with if clauses that display help text if it is associated with the field. The provided template uses `<div>` tags for structure. You can override the template
