That's a lot of configuration, but once you've got it going, you can run your development server and visit any page in your project. Try going to http:localhost:8000/bands/musicians/. If you got all that config right, you'll see a callout on the right side of the page showing all the tools that come with the Debug Toolbar. Figure 13.1 shows the result.

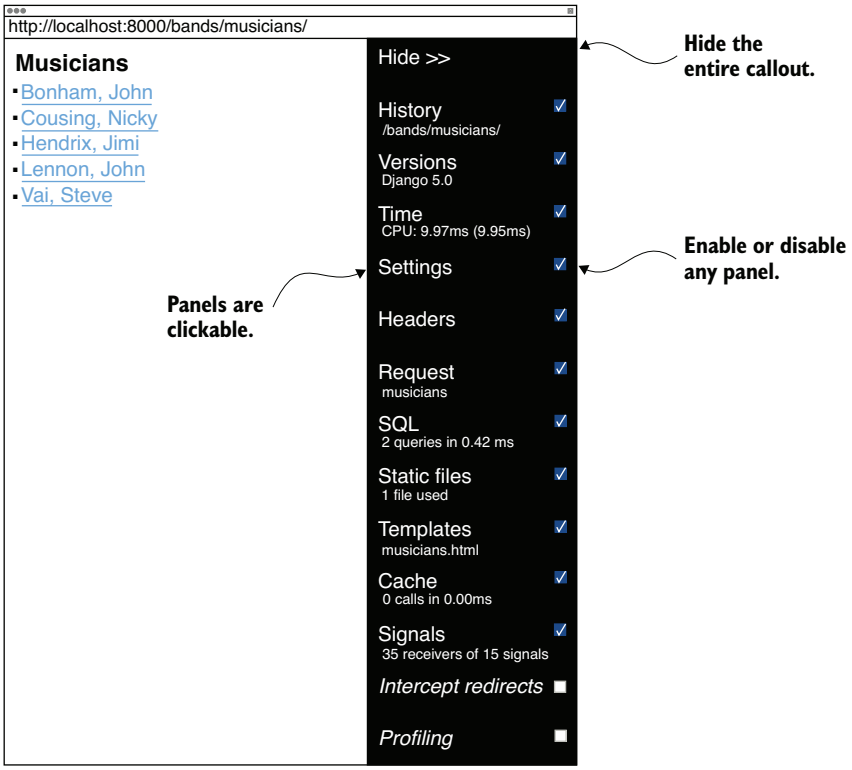

Figure 13.1 Django Debug Toolbar on the musician listing page

The toolbar is composed of a series of reports, with each showing information about the page. The Debug Toolbar calls these mini-reports *panels*, and in fact, you can customize what panels show in your toolbar and even install third-party additions. Gathering debug information can take a bit of time, so for performance reasons, you can turn off any panel using the corresponding check mark.

Some panels show quick information; for example, the Time panel indicates how long it took for the page to show, while the SQL panel tells you how many database queries got run. Clicking a panel opens it, covering your page and revealing detailed information. Table 13.1 describes each of the panels that come with the Debug Toolbar by default.
